Definition - A *graph* is a data structure represented as an ordered pair,  $G = (V, E)$  where  $V$  is a set of nodes and  $E$  is a set of edges that pairwise connect them, i.e., we represent an edge  $e \in E$  as a two-element subset of  $V$ :  $e = \{u, v\}$  for some  $u, v \in V$  where we call  $u$  and  $v$  the *ends* of  $e$ .

The definition given above is for an *undirected graph*, (the default assumption for a graph).

A *directed graph* is a graph,  $G = (V, E)$  where  $E$  is a set of edges that are represented by ordered pairs,  $e = (u, v)$  for some  $u, v \in V$  where  $u$  is the tail of the edge,  $v$  is the head of the edge, and  $e$  is said to leave  $u$  and end at  $v$ .

## Example of Graph - Transportation Network

Transportation Network:

- Nodes - airports
- Edges - an edge from node  $u$  to  $v$  implies there exists a non-stop flight from  $u$  to  $v$ .
- Even though this structure implies a directed graph, there is almost always a return flight in the opposite direction.
- Typically, there are a small number of hubs with a large number of incident edges.
- It is possible to travel between any two nodes in a small number of hops.

## Example of Graph - Communication Network

Communication Network:

- Nodes - computers
- Edges - an edge from node  $u$  to  $v$  implies there exists a *physical link* from  $u$  to  $v$ .

## Example of Graph - Information Network

Information Network:

- Nodes - web pages
- Edges - hyperlinks - an edge from node  $u$  to  $v$  implies there exists a *hyperlink* (directional) from  $u$  to  $v$ .
- The structure of these hyperlink graphs *used to* imply the most important pages on a topic, and was the basis of Google's Page-Rank Algorithm.

## Example of Graph - Social Network

### Social Network:

- Nodes - people
- Edges - could mean a number of different things:
  - 1  $u$  and  $v$  are friends with each other.
  - 2 a romantic relationship (undirected)
  - 3  $u$  seeks advice from  $v$ .
  - 4  $u$  lists  $v$  in his/her email address book.
  - 5 affiliation, such as in LinkedIn.
- Studied by sociologists extensively to understand the nature of dynamics between people, the concept of an “influencer” in a population, etc.

## Example of Graph - Dependency Network

Dependency Network:

- Nodes - object
- Edges -  $u \rightarrow v \implies u$  is a pre-requisite for  $v$ .
- Edges -  $u \rightarrow v \implies u$  *calls*  $v$  as in a software system.

# Path

**Definition:** A *path*,  $p$ , is a sequence of nodes

$v_1, v_2, v_3, \dots, v_{k-1}, v_k$  such that each consecutive pair,  $v_i, v_{i+1}$  is joined by edge,  $e \in E$ , where  $G = (V, E)$ .

$p$  is often called the path from  $v_1$  to  $v_k$ , or we refer to the  $v_1 - v_k$  path.

A path  $p$  is called *simple* if all its vertices are distinct from each other.

# Cycle

**Definition:** A *cycle*, is a path,  $p = v_1, v_2, v_3, \dots, v_{k-1}, v_k$  such that we have the following:

- $k > 2$
- the first  $k - 1$  nodes are all distinct
- $v_1 = v_k$

In other words, the sequence of nodes “cycles back” to the node where it began.

# Cycle

All of these definitions carry over naturally to directed graphs, with the following change: in a directed path or cycle, each pair of consecutive nodes has the property that  $(v_i, v_{i+1})$  is an edge.

# Connectivity

**Definition:** An undirected graph is *connected* if for every pair of nodes,  $u$  and  $v$ , there is a path from  $u$  to  $v$ .

**Definition:** A directed graph is *strongly connected* if for every two nodes,  $u$  and  $v$  there is a path from  $u$  to  $v$  and a path from  $v$  to  $u$ .

**Definition:** The *distance* between  $u$  and  $v$  is the *minimum* number of edges between  $u$  and  $v$ .

## Definition - Tree

**Definition:** An undirected graph is a *tree* if it is connected and does not contain a cycle.

In a strong sense, trees are the simplest kind of connected graph - deleting any edge from a tree will disconnect it.

## Tree - Other Definitions

- For thinking about the structure of tree  $T$ , it is useful to *root* it at a particular node,  $r$ . Physically, this is the operation of grabbing  $T$  at the node  $r$  and letting the rest of it hang downward under the force of gravity, like a mobile.
- We “orient” each edge of  $T$  away from  $r$ .
- **Definition:** For each other node,  $v$ , we declare the *parent* of  $v$  to be the node  $u$  that directly precedes  $v$  on its path *away* from  $r$ .
- **Definition:** We declare node  $w$  to be a *child* of  $v$  if  $v$  is the parent of  $w$ .

## Tree - Two Drawings

**Figure 3.1** Two drawings of the same tree. On the right, the tree is rooted at node 1.

- The idea of *rooting* a tree encodes the notion of a *hierarchy*.
- Rooting a tree,  $T$  also makes certain concepts easier to grasp.  
For example:
  - For a given tree of  $n$  nodes, how many edges does it have?
  - Each node other than the root has a single edge leading “upward” to its parent, and conversely, each edge leads upward from precisely one non-root node.
  - Thus, every  $n$ -node tree has exactly  $n - 1$  edges.

(3.1) Every  $n$ -node tree has exactly  $n - 1$  edges.

(3.2) Let  $G$  be an undirected graph on  $n$  nodes. Any two of the following statements implies the third:

- ①  $G$  is connected.
- ②  $G$  does not contain a cycle.
- ③  $G$  has exactly  $n - 1$  edges.
